Technical Data Sheet

Grilon, Grilamid and Grivory – Resistance to Chemicals

Modern day life and technology is unimaginable without plastic materials. It is a prerequisite, however that for each individual application, a plastic material is selected that is not affected by the media to which it is exposed.

In general, polyamides exhibit very good resistance to all kinds of chemicals. Apart from concentrated acids, only very few reagents attack polyamides.

The information about resistance to chemicals given in this leaflet is intended to help achieve optimal material selection.

EMS-GRIVORY

Influencing factors

Within the family of engineering plastics, polyamides are characterised by very good resistance to chemicals. The chemical resistance of a plastic material is dependent on its molecular structure, the nature of the surrounding media (e.g. acidic or alkaline solutions, polar or non-polar solvents), the concentration of the reagents, the kind and duration of contact as well as the ambient temperature.

Kinds of chemical

Certain chemicals can induce physical or chemical damage to plastics. To what degree this takes place, depends amongst others on the chemical nature. Physical processes such as swelling are generally reversible whereas chemical attack can lead to irreversible changes in the material. Oxidation, for example, can cause the material to decompose.

Concentration of contact media

The higher the concentration of the active substances, the faster early fatigue of the polymeric material may occur.

Temperature

The application temperature has a direct influence on the resistance to chemicals. The higher the surrounding temperature, the greater and more rapid the effects of chemical attack are.

Types of exposure and duration

Along with the type of exposure (on one side, both sides, permanent or short-term contact) the chemical resistance of the plastic is influenced by the duration of the exposure. The longer the contact time, the stronger the effect of the chemicals on the material is.

The following table describes the resistance to chemicals of the following types of material:

Grilon	polyamide 6 and 66
Grilamid L	polyamide 12
Grilamid S	polyamide 610 and 1010
Grilamid D	polyamide 612
Grilamid TR	transparent polyamides
Grivory G	partially aromatic, amorphous polyamides, unreinforced
Grivory GV	semi-crystalline, partially aromatic polyamides, reinforced
Grivory HT	polyphthalamide

The resistance tests were carried out on ISO standard test bars which were stored in the chemicals at room temperature for up to 12 months. This means that evaluation of material resistance is based on static storage of test specimens in a stress-free state. For deviating conditions in practical use, consultation is recommended. Characteristic properties such as change in weight, length, tensile stress and elongation at break of the test bars after aging in the diverse media served as test criteria.

As resistance to chemicals is primarily dependent on the basis polymer, the information applying to unreinforced grades is also valid for reinforced material groups.

Key for qualitative evaluation of the material resistance:

●●● Resistant
No or little reversible change in weight and/or dimensions possible

●● Limited resistance
Changes in weight, dimension or even irreversible changes to property values possible after longer exposure; consultation recommended

● Not resistant
May be used under specific conditions, e.g. short-term contact

○ Strong attack or soluble

The concentration values given in the table refer to the maximum concentration of the medium at which the material was tested. It can be assumed that the same or better resistance is achieved with less concentrated reagents.
Some additives may be extracted by the media. In the case of plasticizers, the loss of flexibility is usually compensated for by uptake of the media.

Stress corrosion cracking of amorphous polyamides

Amorphous polyamides such as Grilamid TR and Grivory G can develop stress cracking when exposed to certain media. External stresses are caused by the influence of forces on the component, while internal stresses may be caused through incorrect processing.

Further information on stress corrosion cracking can be found in the corresponding product brochures. The brochure "Grilamid TR" in particular, gives details of the compatibility of different transparent material variants and their tendency to form stress cracking when in contact with specific solvents.

Hydrolysis resistance

All polyamides take up water when kept in a moist environment. At room temperature this is a physical process which is reversible. Irreversible chemical damage to the material can only be caused by water or aqueous solutions at high temperatures. This is referred to as hydrolysis.

Water uptake is mainly dependent on the amide group concentration of the individual polyamide type. For this reason, polyamide 12 is considerably more resistant to hydrolysis than polyamide 6 and polyamide 66. The Grivory grades also take up significantly less water and that more slowly than materials made of Grilon.
